CSE331 – Computer Organization

Lecture 9: An Overview of Pipelining

Pipelining

Pipelining provides a method for executing multiple instructions at the same time.

- Laundry Example:
- Ann, Brian, Cathy, Dave each have one load of clothes to wash, dry, and fold
- Washer takes 30 minutes
- Dryer takes 40 minutes
- "Folder" takes 20 minutes

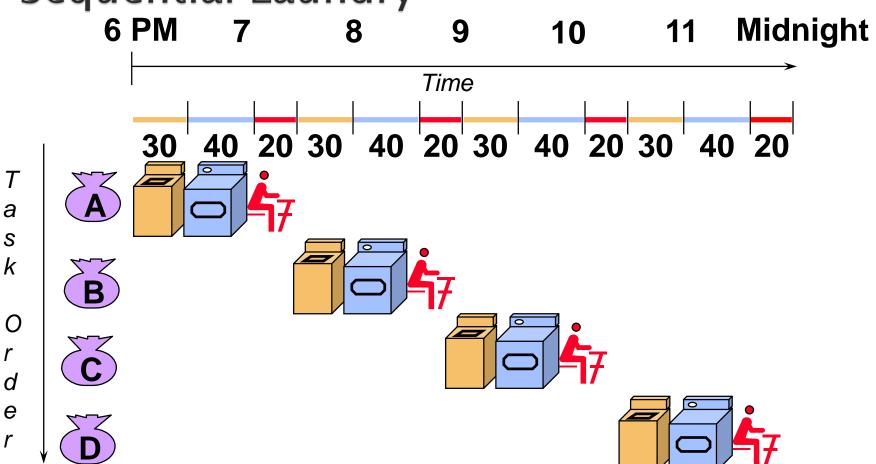

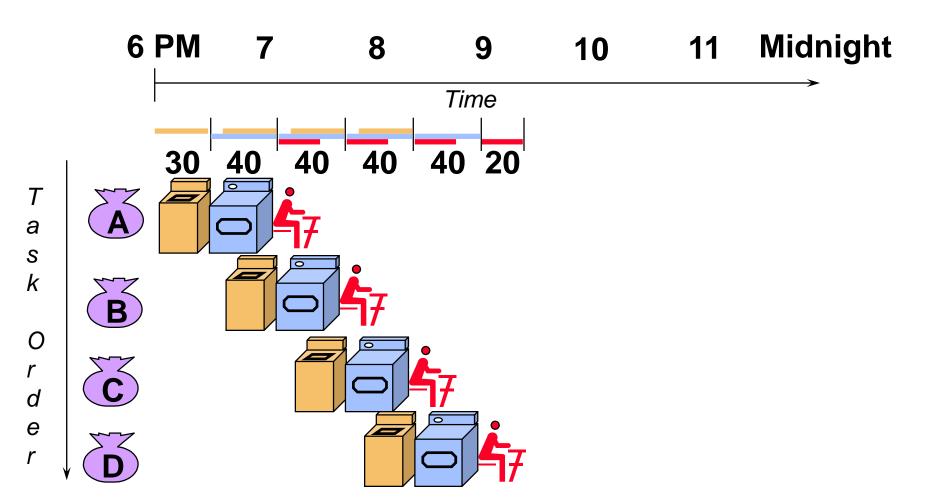

Sequential Laundry

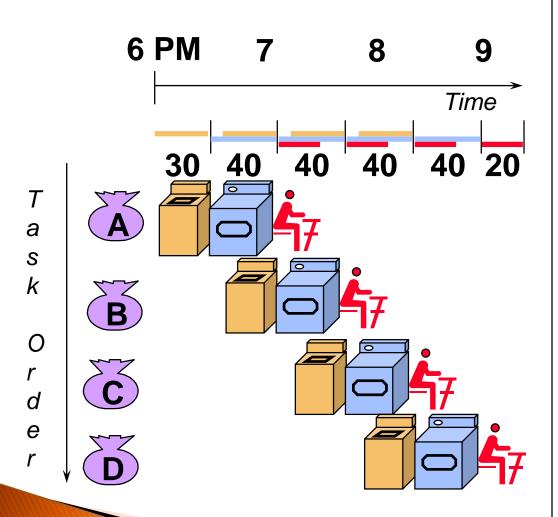

- Sequential laundry takes 6 hours for 4 loads
- If they learned pipelining, how long would laundry take?

Pipelined Laundry: Start work ASAP

Pipelined laundry takes 3.5 hours for 4 loads

Pipelining Lessons

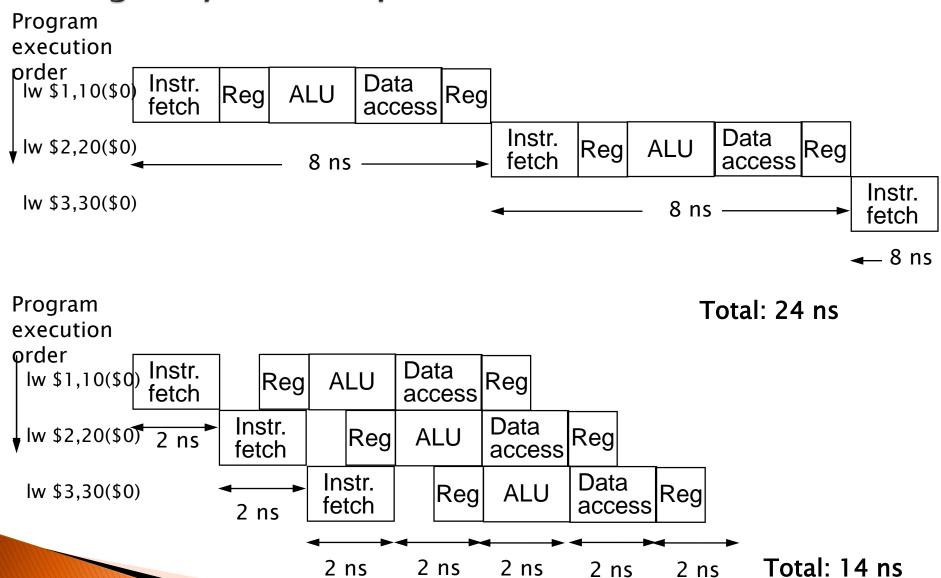

- Pipelining doesn't help latency of single task, it helps throughput of entire workload
- Pipeline rate limited by slowest pipeline stage
- Multiple tasks operating simultaneously using different resources
- Potential speedup = Number pipe stages
- Unbalanced lengths of pipe stages reduces speedup
- Time to "fill" pipeline and time to "drain" it reduces speedup
- Stall for Dependences

Total Time for Eight Instructions

Instr. class	Instr. fetch	Register read	ALU operation	Data access	Register write	Total time
Load word	2 ns	1 ns	2 ns	2 ns	1 ns	8 ns
Store word	2 ns	1 ns	2 ns	2 ns		7 ns
R-type	2 ns	1 ns	2 ns		1 ns	6 ns
Branch	2 ns	1 ns	2 ns			5 ns

R-type instructions: add, sub, and, or, slt

Single Cycle vs. Pipelined Execution

Pipelining Speedup

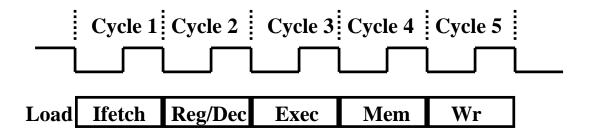

If the stages are perfectly balanced:

```
Time between instructions pipelined = \frac{Time between instructions}{Number of pipeline stages}
```

- Potential speedup = Number of pipeline stages
- In previous example, 3 instructions takes 14 ns.
 If we would add 1000 instructions then each instruction will add 2 ns to the total execution time:

```
Total execution time _{pipelined} = 14 + 2000 = 2014 ns
Total execution time _{nonpipelined} = 1003 * 8 = 8024 ns
8024 / 2014 = 3.98 \sim 8 / 2
```

The Five Stages of the Load Instruction

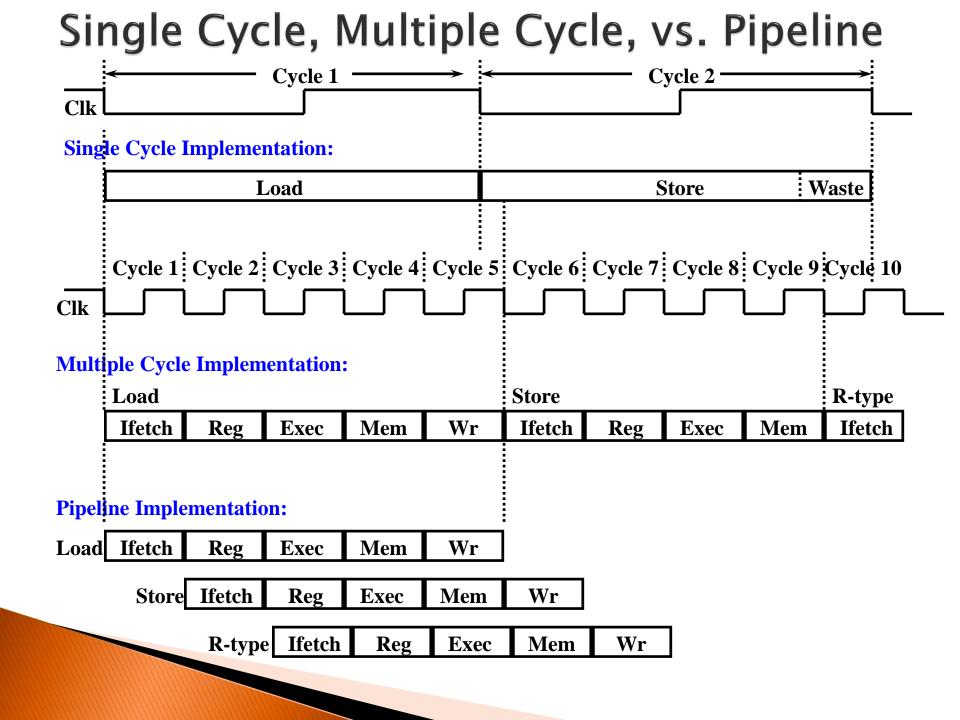

- Ifetch: Instruction Fetch
 - Fetch the instruction from the Instruction Memory
- Reg/Dec: Registers Fetch and Instruction Decode
- **Exec**: Calculate the memory address
- Mem: Read the data from the Data Memory
- ▶ **Wr**: Write the data back to the register file

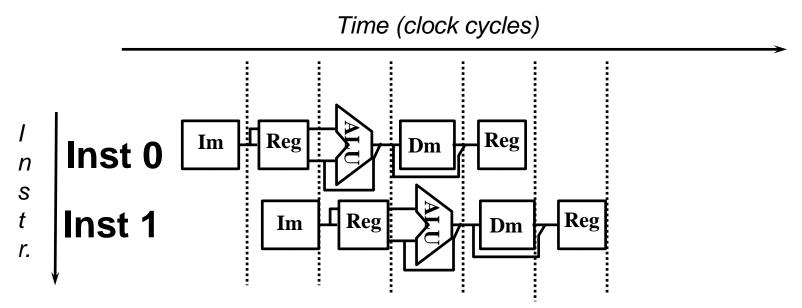

Pipelined Execution

Time IFetch | Dcd Exec WB Mem IFetch Dcd Exec Mem **WB** IFetch Dcd Exec Mem **WB** IFetch Dcd Mem **WB** Exec IFetch Dcd Exec Mem **WB Program Flow** IFetch | Dcd Exec Mem WB

- On a processor multiple instructions are in various stages at the same time.
- Assume each instruction takes five cycles

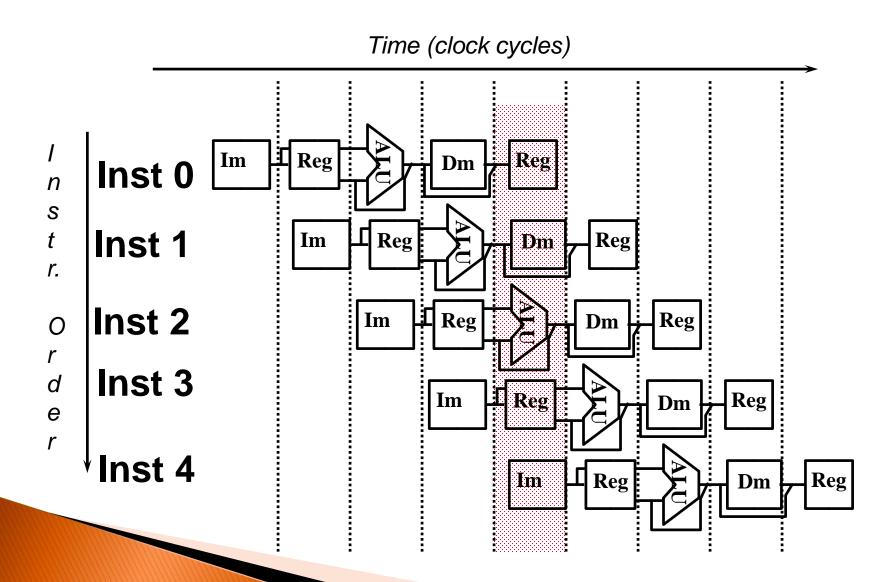

Graphically Representing Pipelines

- Can help with answering questions like:
 - How many cycles does it take to execute this code?
 - What is the ALU doing during cycle 4?
 - Are two instructions trying to use the same resource at the same time?

Why Pipeline? Because the resources are there!

Why Pipeline?

- Suppose
 - 100 instructions are executed
 - The single cycle machine has a cycle time of 45 ns
 - The multicycle and pipeline machines have cycle times of 10 ns
 - The multicycle machine has a CPI of 3.6
- Single Cycle Machine
 - 45 ns/cycle x 1 CPI x 100 inst = 4500 ns
- Multicycle Machine
 - 10 ns/cycle x 3.6 CPI x 100 inst = 3600 ns
- Ideal pipelined machine
 - 10 ns/cycle x (1 CPI x 100 inst + 4 cycle drain) = 1040 ns
- Ideal pipelined vs. single cycle speedup
 - 4500 ns / 1040 ns = 4.33
- What has not yet been considered?

Can pipelining get us into trouble?

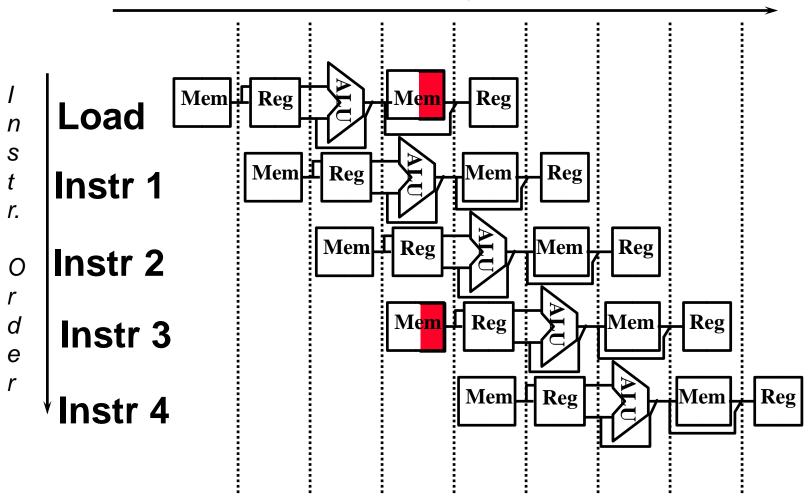

- Yes: Pipeline Hazards
 - structural hazards: attempt to use the same resource (hardware unit) two different ways at the same time
 - E.g., two instructions try to read the same memory at the same time
 - data hazards: attempt to use item before it is ready
 - instruction depends on result of prior instruction still in the pipeline

```
add r1, r2, r3 sub r4, r2, r1
```

- control hazards: attempt to make a decision before condition is evaluated
 - branch instructions beq r1, r2, loop add r3, r4, r5
- Can always resolve hazards by waiting
 - pipeline control must detect the hazard
 - take action (or delay action) to resolve hazards

Single Memory is a Structural Hazard

Time (clock cycles)

Detection is easy in this case! (right half highlight means read, left half write)

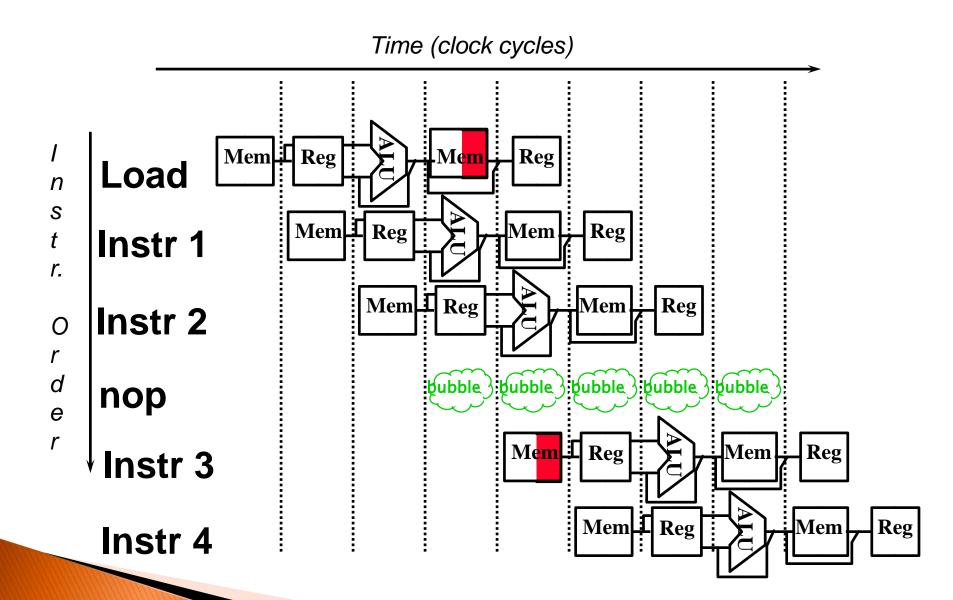

What's the Solution?

Solution 1: Use separate instruction and data memories

Solution 2: Allow memory to read and write more than one word per cycle

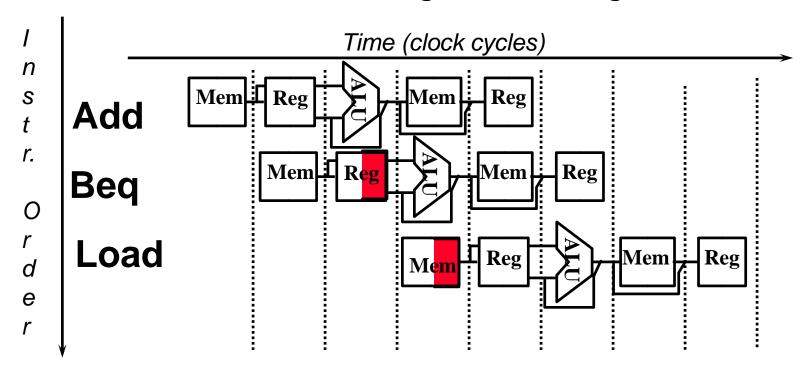

Solution 3: Stall

Solution 3: Stall

Control Hazard Solutions

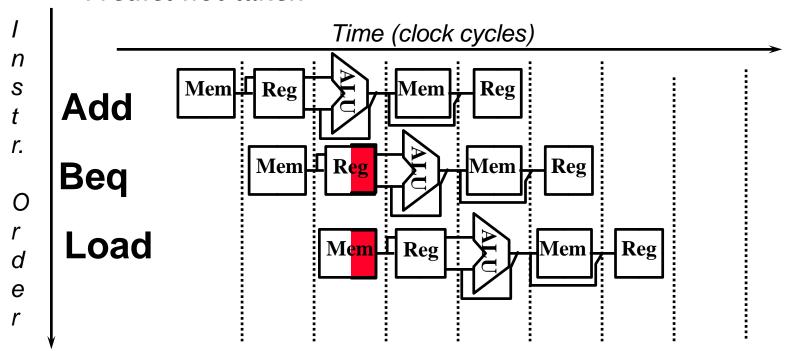

- Stall: wait until decision is clear
 - It is possible to move up decision to 2nd stage by adding extra hardware to check registers as being read

Impact: 2 clock cycles per branch instruction => slow

Control Hazard Solutions

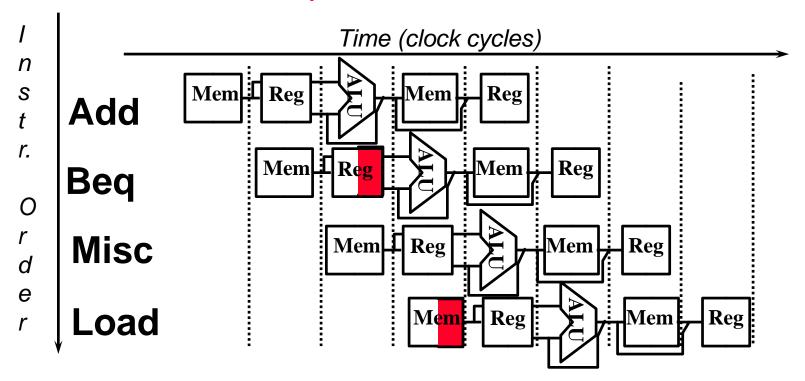

- Predict: guess one direction then back up if wrong
 - Predict not taken

- Impact: 1 clock cycle per branch instruction if right, 2 if wrong (right 50% of time)
- More dynamic scheme: history of 1 branch (90%)

Control Hazard Solutions

Redefine branch behavior (takes place after next instruction) "delayed branch"

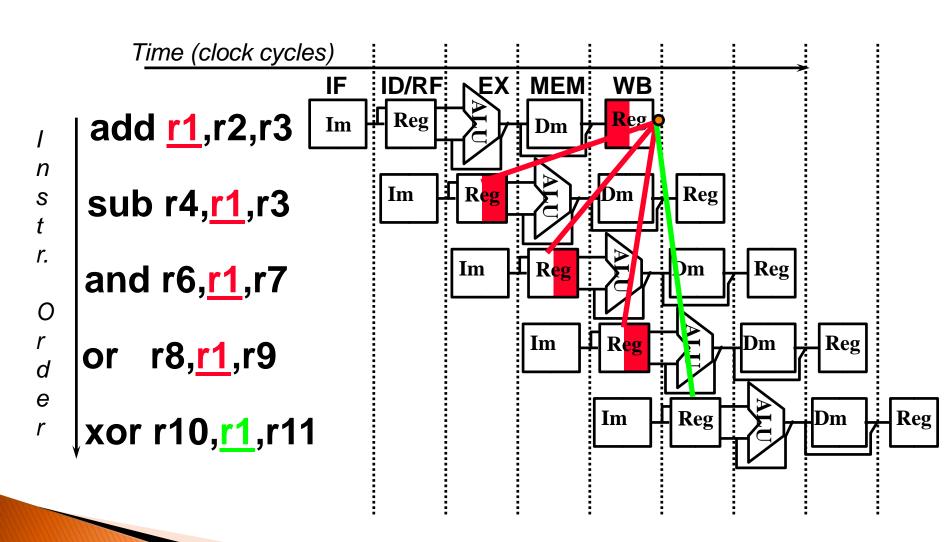

Impact: 1 clock cycles per branch instruction if can find instruction to put in "slot" (50% of time)

Data Hazard on r1

Problem: r1 cannot be read by other instructions before it is written by the add.

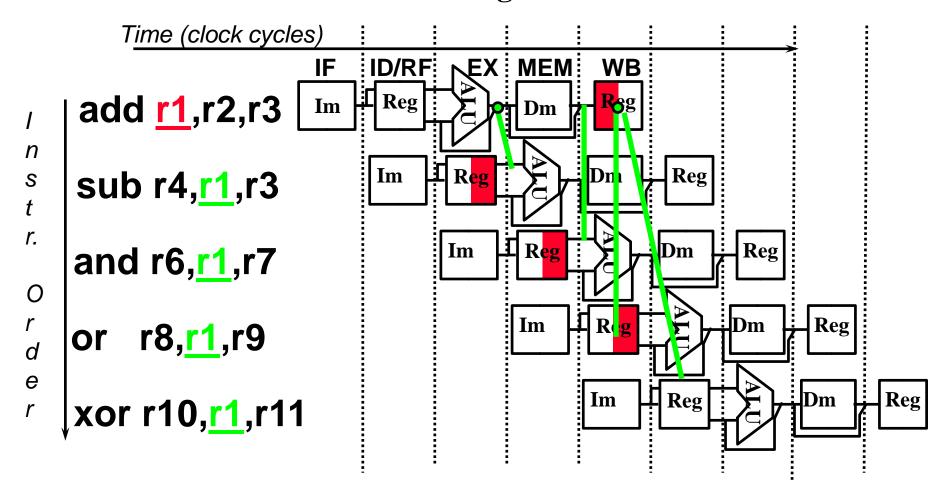

Data Hazard on r1:

Dependencies backwards in time are hazards

Data Hazard Solution:

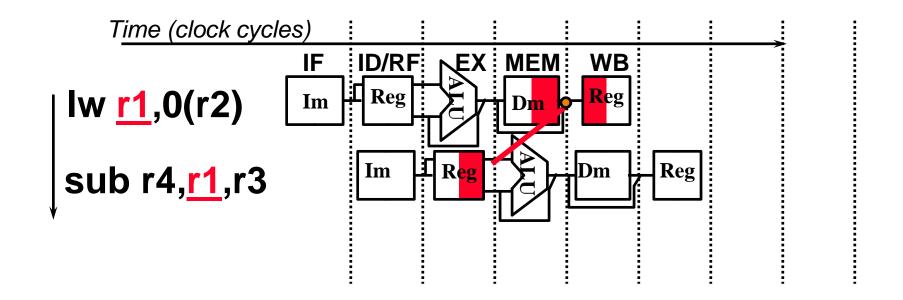

"Forward" result from one stage to another

• "or" instruction is OK if define read/write properly

Forwarding (or Bypassing): What about Loads

Dependencies backwards in time are hazards

- Can't solve with forwarding:
- Must delay/stall instruction dependent on loads
